Most widely studied case: approximation of a function $f(x)$ over an interval $\Delta = [a, b] \subset \mathbb{R}$ by C^r piecewise polynomials.

- Subdivide $\Delta = [a, b]$ into subintervals:
$$\Delta = [a_0, a_1] \cup [a_1, a_2] \cup \cdots \cup [a_{n-1}, a_n]$$
- Find a basis for the vector space $C_d^r(\Delta)$ of C^r piecewise polynomial functions on Δ with degree at most d (e.g. B-splines)
- Find best approximation to $f(x)$ in $C_d^r(\Delta)$

C^0 for Simplicial Splines [Billera-Rose '92]

$$C^0(\widehat{\Delta}) \cong A_{\Delta}, \text{ the face ring of } \Delta.$$

Why is this an isomorphism?

- Send x_v to tent function at vertex v .
- Product of tent functions is zero if correspond to nonface.

Consequences:

- $C^0(\widehat{\Delta})$ is entirely combinatorial!
- $\dim C_d^0(\Delta) = \sum_{i=0}^n f_i \binom{d-1}{i}$ for $d > 0$, where $f_i = \# i\text{-faces of } \Delta$.
- If Δ is homeomorphic to a disk, then $C^0(\widehat{\Delta})$ is free as a $S = \mathbb{R}[x_0, \dots, x_n]$ module.
- If Δ is shellable, then degrees of free generators for $C^0(\widehat{\Delta})$ as S -module can be read off the h -vector of Δ .

A partition of a domain D is called a *cross-cut partition* if the union of its two-cells are the complement of a line arrangement.

- Basis for $C_d^r(\Delta)$ and $\dim C_d^r(\Delta)$ [Chui-Wang '83]
- $C^r(\widehat{\Delta})$ is free for any r [Schenck '97]

Theorem: Linearizing $\dim C_d^r(\Delta)$ [D.-Sottile-Sun '16]

Let Δ consist of n irreducible curves of degree d_1, \dots, d_n meeting at $(0, 0)$ with distinct tangents and no common zero in $\mathbb{P}^2(\mathbb{C})$ other than $(0, 0)$. Then, for $d \gg 0$,

$$\begin{aligned}\dim C_d^r(\Delta) &= \dim C_d^r(\Delta_L) \\ &+ \sum_{i=1}^n \left(\binom{d+2-d_i(r+1)}{2} - \binom{d-r-1}{2} \right)\end{aligned}$$
